Write the program which handles below task.

1) Open File

- Accept file name from user and open it using `open()`.
- Print: success message + returned file descriptor.
- Handle errors using `perror()`.

2) Open File in Given Mode

- Accept file name and mode (`R`, `W`, `RW`, `A`) from user.
- Convert mode to flags (`O_RDONLY`, `O_WRONLY`, `O_RDWR`, `O_APPEND | O_CREAT`).
- Open file accordingly and display fd.

3) Check File Access Permission

- Accept file name and mode (read/write/execute).
- Use `access()` to check permission for current process.
- Print "Accessible / Not accessible" with reason.

4) Display Complete File Information

- Accept file name and display file metadata using `stat()`:
  - Size, inode, permissions, hard links, owner uid/gid, file type, last access/modify time.

5) Read N Bytes From File

- Accept file name and number of bytes `N`.
- Read exactly `N` bytes using `read()` and print on console.
- If file contains less than `N`, print only available bytes
