Write the program which handles below task.

1 Directory Traversal Basics
Create a program `ls_clone.c` that takes one directory path and prints:

- Entry name
- Type (file/dir/link/other)
- Size (bytes)
- Permissions in `rwxr-xr-x` format
- Last modified time
- Skip `.` and `..`.
- Build full path using `snprintf(dir + "/" + name)`.

2 Recursive Directory Traversal
Write `tree_clone.c` which prints a directory as a tree, like:

```
root/
  a.txt
  src/
    Ganesh.c
```

- Indentation based on recursion depth
- Print type markers:
  - `[D]` directory
  - `[F]` regular file
  - `[L]` symbolic link
- Use `lstat()` to detect symbolic links.
- Do not follow symlink directories (avoid loops).

3 File Counter + Size Report
Create `dir_report.c` that recursively calculates:

- Total number of files
- Total number of directories
- Total size of regular files (in bytes)
- Largest file name + size
- Count a directory when you enter it.
- For size: consider only regular files (`S_ISREG`).

- Ignore symlink target size (treat symlink as link object only).

Output:

```
Files: 120
Dirs : 15
Total Size: 9823412 bytes
Largest: Marvellous.mp4 (2341123 bytes)
```
